

Generating Code for the Virtual Machine VM

A small example

Daniela Carneiro da Cruz Pedro Rangel Henriques

The purpose of this document is twofold. On one hand we want to present an example of a VM program in its assembly language; that program shows how to use a subset of assembly instructions, and illustrates their operational semantics.

On the other hand we intend to illustrate a translation scheme from a high-level programming language to assembly code.

1 A LISS Source Program

Suppose we have the following program, written in the high-level programming language LISS (Language of Integers, Sequences and Sets), and we want to execute it.

For that it is necessary to translate that program into the code (assembly or binary) of a target machine.

```
"Integers.liiss" 1 ≡  
  
program IntegerTest {  
  
    Declarations  
  
        intA := 4, intB, intC := 6 -> integer;  
        c := [1,2,3], vector -> Array size 8;  
        flag := false -> boolean;  
  
    Statements  
  
        intA = -3 + intC * (7 + c[1]);  
        writeLn(c);  
        c[5] = 1;  
  
        /* logic operations */  
  
        bool = !( (intA == intB) || (intA != intC) && (c[1] < 6) ) || flag;  
    }  

```

2 Generated VM Code

To run the program above in the VM virtual machine, it should be translated to VM assembly code, either manual or automatically.

Bellow, we list the code generated by our LissCompiler.

```
